

cybersecurity — for the home —

You don't have to be a computer expert to guard your home computer system against cybercriminals, you just need to follow this straight-forward procedure that consists of three critical elements: **Isolate | Update | Defend**™

— isolate —

First, identify and isolate the data that is valuable to you. Such as, banking info, personal info, photos, videos, etc., and back-up these files to removable media.

— update —

Next, make sure that your operating system and browser, and other software have the latest patches installed and have automatic updates turned on.

— defend —

Finally, you should strengthen the security of your computer by installing up-to-date antivirus software, applying proper security settings to your router, and fortify against outside intrusion by using a firewall.

With the Isolate, Update, & Defend tasks completed you will have done much of the work needed to safeguard your data in the home.
